Human infection with avian influenza A(H5) viruses

Human infection with avian influenza A(H5N1) virus
Between 11 August and 17 August 2017, no new cases of human infection with avian influenza A(H5N1) virus were reported to WHO in the Western Pacific Region.

As of 17 August 2017, a total of 238 cases of human infection with avian influenza A(H5N1) virus were reported from four countries within the Western Pacific Region since January 2003 (Table 1). The last case was reported on 14 January 2016. Of these cases, 134 were fatal, resulting in a case fatality rate (CFR) of 56%.

Table 1: Cumulative number laboratory-confirmed human cases (C) and deaths (D) of influenza A(H5N1) virus infection reported to WHO (January 2003 to 17 August 2017), Western Pacific Region.

Globally, from January 2003 to 17 August 2017, there were 859 cases of human infection with avian influenza A(H5N1) virus reported from 16 countries worldwide. Of these cases, 453 were fatal, resulting in a CFR of 52.7%.

Human infection with avian influenza A(H5N6) virus
Between 11 August and 17 August 2017, no new cases of human infection with avian influenza A(H5N6) virus were reported to WHO in the Western Pacific Region. The last case was reported on 1 December 2016 (source: [http://www.who.int/csr/don/07-december-2016-ah5n6-china/en/](http://www.who.int/csr/don/07-december-2016-ah5n6-china/en/)). A total of 16 laboratory-confirmed cases of human infection with influenza A(H5N6) virus, including six deaths, have been reported to WHO from China since 2014.

Public health risk assessment for human infection with avian influenza A(H5) viruses
Whenever avian influenza viruses are circulating in poultry, sporadic infections and small clusters of human cases are possible in people exposed to infected poultry or contaminated environments; therefore sporadic human cases are not unexpected.

With the rapid spread and magnitude of avian influenza outbreaks due to existing and new influenza A(H5) viruses in poultry in areas that have not experienced this disease in poultry recently, there is a need for increased vigilance in the animal and public health sectors. Community awareness of the potential dangers for human health is essential to prevent infection in humans. Surveillance should be enhanced to detect human infections if they occur and to detect early changes in transmissibility and infectivity of the viruses.

Human infection with avian influenza A(H7N9) virus in China

Between 11 August and 17 August 2017, no new cases of human infection with avian influenza A(H7N9) virus were published in Disease Outbreak News. The cases reported in the most recent publication in Disease Outbreak News (dated 7 August 2017) were notified to WHO on 11, 14 and 21 July 2017, respectively (Source: http://www.who.int/csr/don/07-august-2017-ah7n9-china/en/). As of 17 August, a total of 1,557 laboratory-confirmed human infections with avian influenza A(H7N9) virus have been reported to WHO since early 2013 and published in Disease Outbreak News.

China CDC reported on 30 June 2017 that during the fifth wave (since October 2016), 25 human cases were infected with highly pathogenic avian influenza (HPAI) A(H7N9) virus, which had changes in the hemagglutinin gene indicating a change to high pathogenicity in poultry. Mean age of these 25 patients was 57 years old (range: 17-80) and 16 were male. Onset dates of illness ranged from 17 December 2016 to 14 March 2017, and were from Guangdong (8), Guangxi (12), Hunan (4), and Taiwan (1, the case had travel history to Guangdong). No increased transmissibility or virulence to human cases has been detected related to the HPAI A(H7N9) virus (http://www.chinaivdc.cn/cnic/en/Surveillance/WeeklyReport/201706/t20170630_144621.htm). No further HPAI cases have been reported since 30 June 2017.

WHO is continuing to assess the epidemiological situation and will conduct further risk assessments as new information becomes available. The number and geographical distribution of human infections with avian influenza A(H7N9) viruses in the fifth epidemic wave (since October 2016) is greater than previous waves.

Further sporadic human cases of avian influenza A(H7N9) virus infection are expected in affected and possibly neighbouring areas. Should human cases from affected areas travel internationally, their infection may be detected in another country during or after arrival. However, if this were to occur, community level spread is considered unlikely as the virus does not have the ability to transmit easily among humans.

To date, there has been no evidence of sustained human-to-human transmission of avian influenza A(H7N9) virus. Human infections with the A(H7N9) virus are unusual and need to be monitored closely in order to identify changes in the virus and transmission behaviour to humans as this may have serious public health impacts.

Animal infection with avian influenza virus

Between 10 August and 17 August 2017, there were 2 outbreaks of HPAI reported by OIE: HPAI A(H5N1) in five farms in Lao PDR and HPAI A(H5N6) in a poultry farm in Philippines.

HPAI A(H5N1) outbreak in Lao PDR

New outbreaks of HPAI A(H5N1) infection in poultry were reported in Phienta, Pu, Hadsamkhone and Nasong in Thanthome district, Xaysomboun Special Region and Donglankham in Sanasomboun district, Champasak. The outbreak started on 2 July 2017, and is still ongoing. A total of 14,495 birds out of 19,336 susceptible birds have died and the remaining 4,841 have been culled as a control measure.
HPAI A(H5Ny) outbreak in Philippines

One new outbreak of HPAI A(H5Ny) infection in poultry was reported in San Luis, Pampanga province, Philippines. The reported outbreak began on 24 July 2017, and is still ongoing. A total of 36,485 birds out of 190,000 susceptible birds have died.
